

AI-Assisted Analysis

Using a Claude Code skill to facilitate Example Mapping with QA, BA, and PO.

Background: Example Mapping

A structured analysis technique (Matt Wynne)

- **Story** (yellow): what we're building
- **Rules** (blue): the constraints that govern it
- **Examples** (green): concrete scenarios in Given/When/Then
- **Questions** (red): the things we don't know yet

The goal is to leave the room with agreement rather than assumptions.

The Tool

/analyse CSUB-1212

A Claude Code skill that:

1. Reads the story, parent epic, and sibling stories from Jira
 2. Generates a draft Example Map from that context
 3. Runs an interactive session with the group — presenting, revising, confirming
 4. Writes the agreed output back to Jira
-

Story One: Remove the Feedback Prompts

CSUB-1212

The extraction feedback UI — asking authors whether AI-extracted content was correct — was confusing 50% of users and not producing useful data for the other 50%.

The skill read the epic and siblings, generated rules and examples, worked through open questions with the group. Ticket went from rough to "Ready for Solution" in one session.

Story Two: Fix the Editorial Policy Links

CSUB-1216

This one was described as "update some links."

In the analysis session, the skill found that `editorialPolicyUri` was hardcoded in a `when` block rather than in the config pipeline, and that the same URI was being used for both the ethics statement and acknowledgements — which should point to different pages. That was enough to know the story was bigger than it looked.

During implementation, it went further: auditing the existing URLs across six brands and finding that several were broken or redirecting to new domains.

In both phases, the AI was prepared to state clearly what needed to change. I was more hesitant. It turned out to be right.

The title hadn't changed but the scope had.

What the Skill Contributed

It didn't write any code. What it did:

- Brought in context from the epic and siblings before we started
- Surfaced the discrepancy between the ticket description and what the system actually did
- Kept the session structured so we covered rules, examples, and open questions
- Wrote a clean, agreed description back to Jira at the end

The group made all the decisions. The skill made sure we had the information to make them.

CSUB-1216: Implemented

When I started implementing, the AI picked up where the analysis had left off. It had absorbed the session output and understood what the story had become.

It also hit the same questions a developer would hit: where should this config live? That uncertainty prompted more questions back to Ruth — the product owner — which led to further expansion and refinement of the ticket before the work was done.

The analysis session didn't close everything down. It opened the right conversations.

Observations

The more interesting outcome was CSUB-1216. Without the analysis session, that story could have been picked up as a small config change and turned into a much messier piece of work mid-implementation.

Live Demo

CSUB-1203

Stop populating the author contribution statement from double anonymous drafts.

A sibling of CSUB-1212 — the audience already knows the epic. Let's see what the tool makes of it.
